

Start here

Running an NGA module on your own machine

You have cloned one NGA module. To run it:

Double-click start.bat

That is the whole setup. The first run takes a few minutes: it installs packages, builds a local database, and fetches and starts your own copy of the **Central MIS**, the sign-in server every module uses. A second window opens for the MIS; keep it open. When both windows show their banner, open the address printed in your module's window.

Before the first run, make sure you have:

- **Node.js 20+** — nodejs.org (the LTS download)
- **Git** — git-scm.com
- **MySQL 8 or XAMPP** — start MySQL in the XAMPP Control Panel first
- **Tupo only:** PostgreSQL 16 and Redis

If you are asked to sign in to GitHub during the first run, that is Git fetching the Central MIS. You need read access to its repository — ask your team lead if it is refused.

Sign in

Click **Sign In** in your module. It takes you to your own Central MIS at `http://localhost:5173`. The 6-digit code it then asks for is **printed on the login page** — no email is sent.

Every account below uses the same password: Admin@1234

Username	Role	What they can do
superadmin	SUPER_ADMIN	Everything, everywhere
dev.admin	ADMIN	School management
dev.headteacher	HEAD_TEACHER	Academic oversight
dev.teacher	TEACHER	Teaches 3 subjects in the current year's main class
dev.classteacher	CLASS_TEACHER + TEACHER	Class teacher of that class, plus the same subjects
dev.student	STUDENT	Enrolled in that class and its subjects
dev.parent	PARENT	Parent of dev.student
dev.accountant	ACCOUNTANT	Finance
dev.staff	STAFF	Support staff
dev.programmanager	PROGRAM_MANAGER	Leads the program that class belongs to

These accounts exist **only in the database on your machine**. Production has none of them, and their `@nga.test` emails cannot receive mail.

In TaskMentor, Tendo and Tupo the same logins work — each module reads the role from the MIS: `dev.teacher` is a teacher there, `dev.student` a student, `superadmin` and `dev.admin` are admins.

Running it again

Run `start.bat` again. It skips whatever is already done and starts in seconds.

Something went wrong?

Read the window that shows the error — each message says what to do. The common ones:

It says	Do this
Could not clone the Central MIS	Your connection dropped, or you lack access. Run <code>start.bat</code> again; ask your lead for access if it repeats
Installing ... failed twice	Connection dropped mid-download. Run <code>start.bat</code> again
MySQL is installed but not accepting connections	Start MySQL in the XAMPP Control Panel, then press a key in that window
Central MIS is still not answering	Look at the Central MIS window — the error is there
Redirect URI not allowed	Another program is using your module's port. Free it and run again — do not change the port

The full guide, including how to reset a database, is `LOCAL_SETUP.md` in the repo root.
